

## Homework 4

---

### 1. Master Theorem

a.  $T(n) = 5T(n/3) + n$

$a = 5, b = 3, d = 1, \quad b^d = 3 < 5 = a$

since  $b^d$  is less than  $a$ , this is recursion dominant

therefore  $\Theta(n^{\log_3(n)})$

b.  $T(n) = 2.7T(n/5) + n^2$

$a = 2.7, b = 5, d = 2, \quad b^d = 25 > 2.7 = a$

since  $b^d$  is greater than  $a$ , this is overhead dominate

therefore  $\Theta(n^2)$

c.  $T(n) = 2T(n-1) + n$

There is no  $b$  in this case and therefore we cannot use the master theorem

d.  $T(n) = 1.1 T(0.2n) + 1 = 1.1 T(n/5) + 1$

$a = 1.1, b = 5, d = 0 \quad b^d = 1 < 1.1 = a$

since  $b^d$  is less than  $a$ , this is recursion dominant

therefore  $\Theta(n^{\log_5(n)})$

e.  $T(n) = 2T(n/2) + n \log n$

$a = 2, b = 2, c = \log_2(2) = 1$

$n^1 \log n = f(n)$  meaning the MT is balanced

therefore  $\Theta(n \log(n))$

$$f. T(n) = 2T(n/2) + n^{1/2}$$

$$a = 2, b = 2, d = \frac{1}{2} \quad b^d \approx 1.414 < 2 = a$$

since  $b^d$  is less than  $a$ , this is recursion dominant

therefore  $\Theta(n^{\log_2(n)})$

$$g. T(n) = 4T(n/2) + (n^4 - n + 10)^{1/2} \approx \Theta(n^2)$$

$$a = 4, b = 2, d = 2 \quad b^d = 4 == 4 = a$$

since  $b^d$  is equal to  $a$ , this is balanced

therefore  $\Theta(n^2 \log_2(n))$

$$h. T(n) = 7T(n/3) + \sum_{i=1}^n i = 7T(n/3) + (n^2 + n)/2$$

$$a = 7, b = 3, d = 2 \quad b^d = 9 > 7 = a$$

since  $b^d$  is greater than  $a$ , this is overhead dominate

therefore  $\Theta(n^2)$

$$i. T(n) = 4T(n/2) + n^n$$

Not in right format to get  $d$ , though  $n^n$  is one of the worst complexities so will assume that is the dominant one.

$$j. T(n) = 8T(n/3) + n^3$$

$$a = 8, b = 3, d = 3 \quad b^d = 27 > 8 = a$$

since  $b^d$  is greater than  $a$ , this is overhead dominate

therefore  $\Theta(n^3)$

## 2. D&C Master Theorem

a. Algo 1       $T(n) = 1 T(n/3) + 1$

$a = 1, b = 3, d = 0$        $b^d = 1 == 1 = a$

Worst case would be if there were no negative numbers in the list as it looks as though the algorithm looks for the first negative number?

$$\Theta(n^{\log_3(n)} \log_3(n))$$

Best case the first element is negative as it makes the recursive call at the front of the list first

b. Algo 2       $T(n) = 2 T(n/2) + 1$

$a = 2, b = 2, d = 0$        $b^d = 1 < 2 = a$  so this is recursive dominant

$$\text{therefore } \Theta(n^{\log_2(n)})$$

Worst case would be same as the best case as this simply looks like it sums all the elements in a list

### 3. Merge Sort

a. Design k way merge sort

MergeSortK(A[0, n-1]):

If  $n > 1$ : # still the same since n is multiple of K

$i = 0$

while  $i < n+1$ : # will be n in the last one

    currentStart = i

$i += k$

    Merge(MergeSortK(A[0, i-1]))

    # should end at  $i = n$

Else:

    Return A

#### b. Worst Case

$$T(n) = k T(n/k) + \Theta(n)$$

$$a = k, b = k, d = 1 \quad b^d = k == k = a$$

therefore the equation is balanced at  $\Theta(n)$

#### c. Better or Worse

Better, in class we discussed that the recursion by 2 is  $\Theta(n \log n)$  and  $\Theta(n)$  is better than that.

We would pick a value of  $k$  depending on the number of pieces we want, this skips the number of recursions for later?

This seems wrong but I am not sure what about it is off.

#### d. Does it run in $\Theta(n)$

Yes it is reasonable since the master theorem showed that  $T(n)$  is balanced.

### 4. Consider Algorithm

The algorithm as written will always return 0 as it adds up a number of zeros equal to the number of nodes (including root)

To correct this we could check if  $\text{left} + \text{right} = 0$  then we would know this is a leaf and could return 1

If  $T = \text{null}$  return 0

Else If  $(\text{LeafCounter}(T_{\text{left}}) + \text{LeafCounter}(T_{\text{right}})) == 0$

Return 1

Else return  $\text{LeafCounter}(T_{\text{left}}) + \text{LeafCounter}(T_{\text{right}})$

Now we have check if this node is null, if this node has children (if not it is a leaf, and if not a leaf, call further down to see where the leaves are.

### 5. Travers Tree

a. Pre

A, B, D, E, C, F

b. In

D, B, E, A, C, F

c. Post

D, E, B, F, C, A

6. Karatsuba Algorithm (  $2101 * 1130$  )

$10^4 axc + 10^2 (ad + bc) + bd$        $a = 21, b = 01, c = 11, d = 30$

$21 \times 11 \cdot 10^4 + (21 \times 30 + 1 \times 11) \cdot 10^2 + 1 \times 30$

$231 \cdot 10^4 + (630 + 11) \cdot 10^2 + 30$

$2,310,000 + 64,100 + 30$

$2,310,000 + 64,130$

**2,374,130**

7. Straassen's Algorithm (left is top of matrix, right is bottom)

$R = 10 \ 41 * 01 \ 21 + 21 \ 10 * 20 \ 13$      $s = 10 \ 41 * 01 \ 04 + 21 \ 10 * 11 \ 50$

$T = 01 \ 50 * 01 \ 21 + 30 \ 21 * 20 \ 13$      $u = 01 \ 50 * 01 \ 04 + 30 \ 21 * 11 \ 50$

$R = 21 \ 25 + 53 \ 20 = 74 \ 45$       **Final Matrix:      7 4 7 3**

$S = 01 \ 08 + 72 \ 11 = 73 \ 19$       **4 5 1 9**

$T = 21 \ 05 + 60 \ 53 = 81 \ 58$       **8 1 3 7**

$U = 04 \ 05 + 33 \ 72 = 37 \ 77$       **5 8 7 7**

8. D&C 2-D Closest Pair

Mergesort =  $\Theta (n \log (n) )$

$T(n) = 2 T(n/2) + \Theta (n \log (n) )$

$$a = 2, b = 2, c = \log_2(2) = 1$$

$n \log(n)$  lower bounded by  $n$  is true so case 3 of master theorem

$$\Theta(n \log(n))$$
